Current Challenges: Modeling Species-Rich Communities

Underlying Assumption: Direct Translation of Predation to Reproduction

Lotka-Volterra

$$dN/dt = bN - cNP$$

$$dP/dt = ceNP - mP$$

Potential Issue: Mismatched Time Scales

Lotka-Volterra

$$\frac{dN}{dt} = bN - cNP$$

$$\frac{dP}{dt} = ceNP - mP$$

Long-term
Predictions

Short-term
Dynamics

Current Challenges: The Modeler-Empiricist Dichotomy

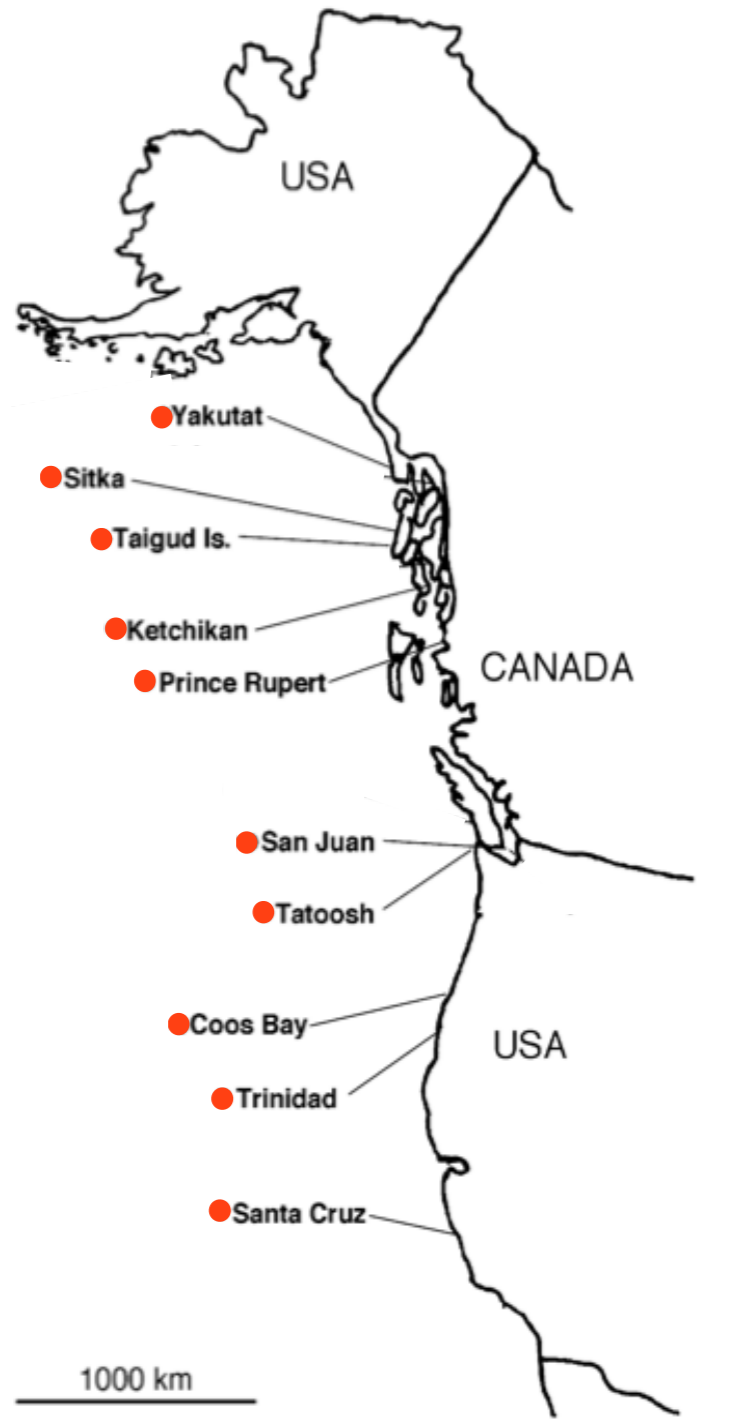

```

Analyze effects of
small perturbations
to communities

Perform large-scale
abundance manipulations
(e.g., species removals)

Current Challenges: “Local Adaptation” and Experimental Scale

Range of *Nucella Ostrina*

adapted from Marko 2004

Ecological Differences across Range

- Biotic factors
 - Prey availability
 - Predator assemblage
 - Competition
- Abiotic environment
 - Temperature
 - Storm severity
- Anthropogenic impacts

Questions

- Can we use short-term predator feeding responses to predict long-term changes in abundance?
- How do predators respond to seasonal patterns of prey reproduction?
- Do results from small-scale abundance manipulations mimic those from species removal experiments?
- How does life history vary across the range of a species?

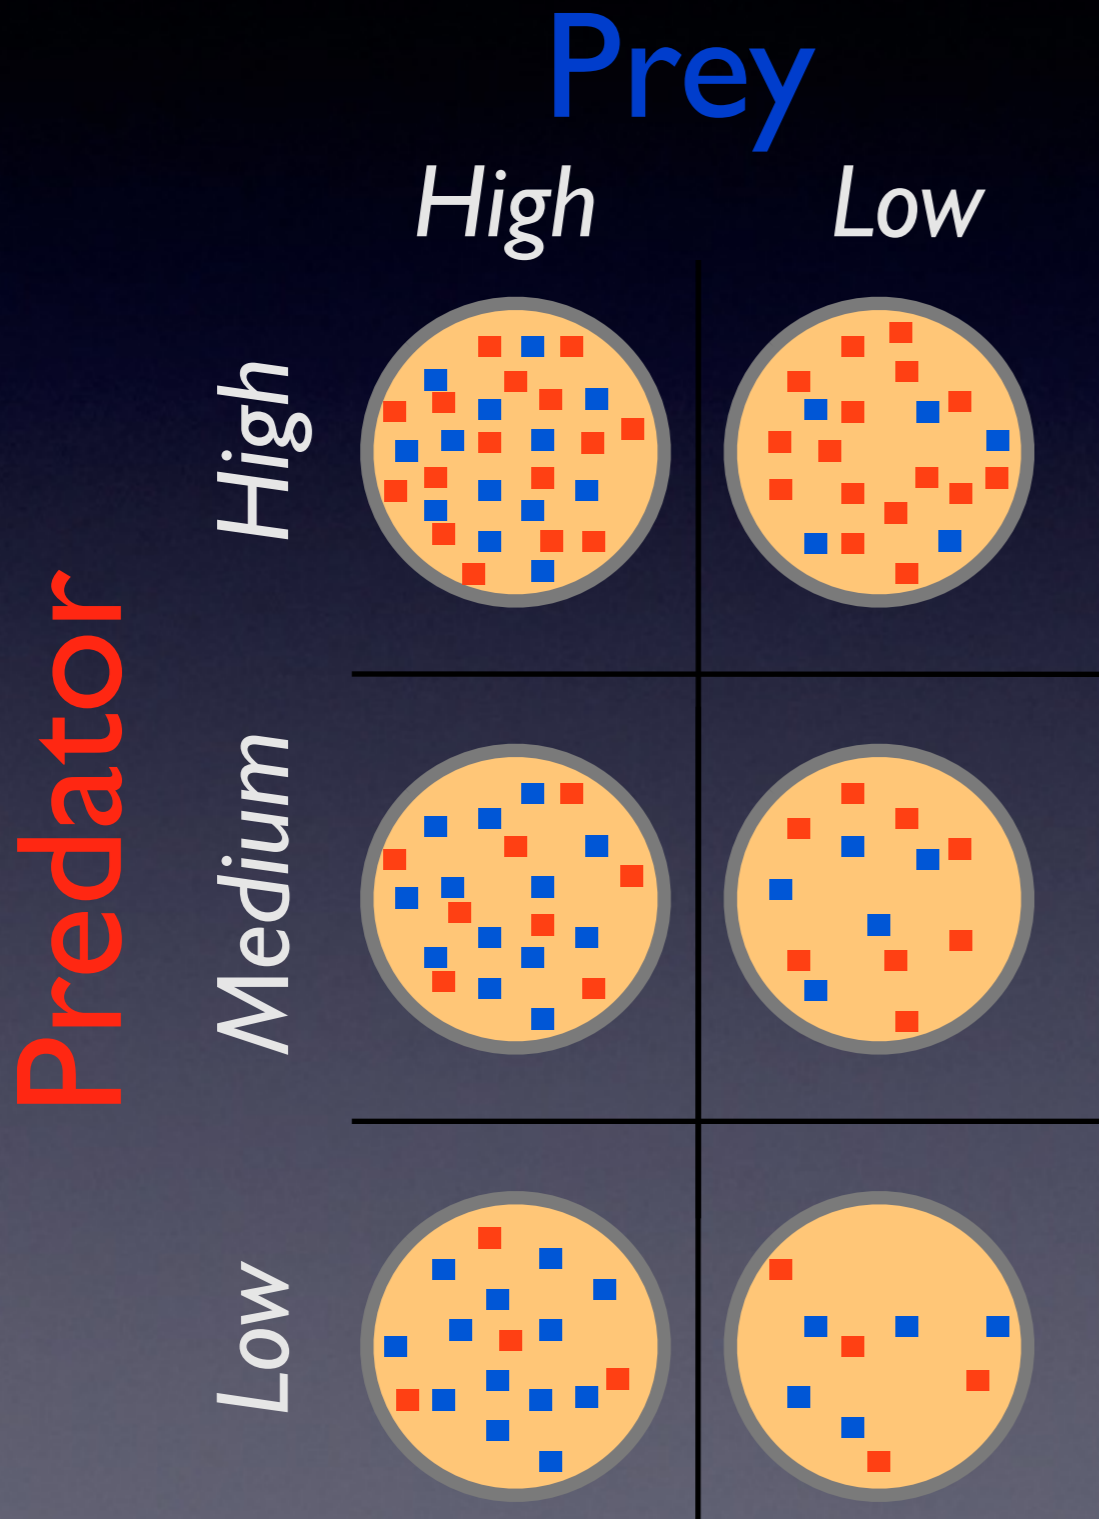

Approach

- Part I: Multi-year tracking of predator responses (feeding, growth, mortality, and reproduction) to manipulations of prey and predator abundance
- Part II: “Natural experiment” that assesses how predators respond to regional differences in the seasonality of prey reproduction

Focal Predator: *Nucella ostrina*

Part I: Density Manipulations

General model structure for assessing
predator responses:

$$\alpha + \beta_1 \text{whelks} + \beta_2 \text{prey} + \beta_3 \text{whelks} \times \text{prey}$$

Effects on Whelks: Growth

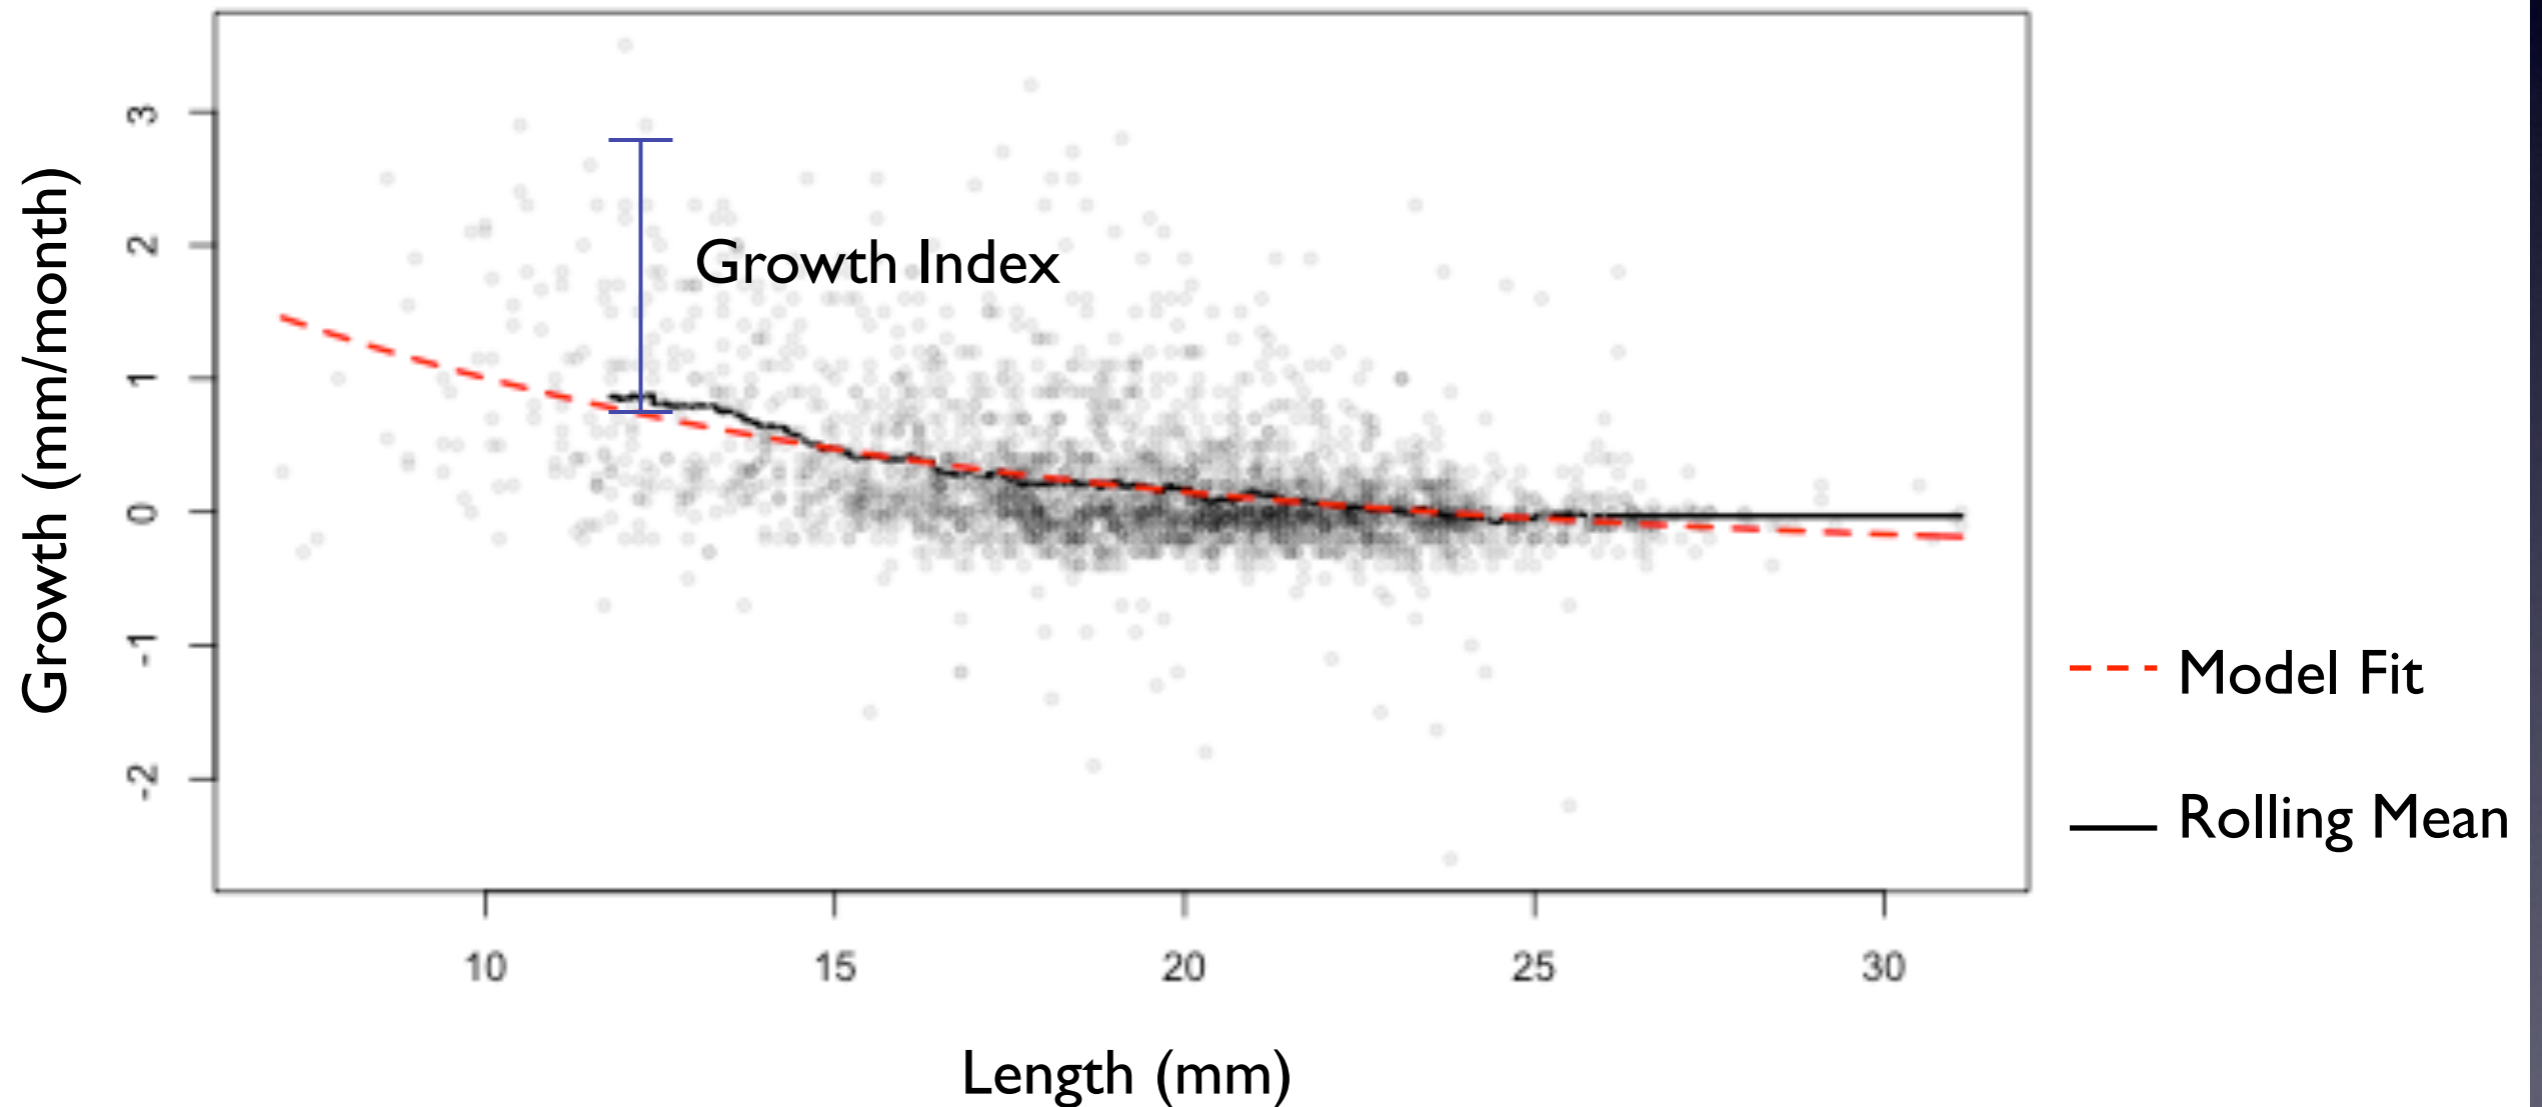

Challenge: Size-Dependent Growth

Growth by Shell Length

Solution: Use “Growth Index” for Analysis

Growth by Shell Length

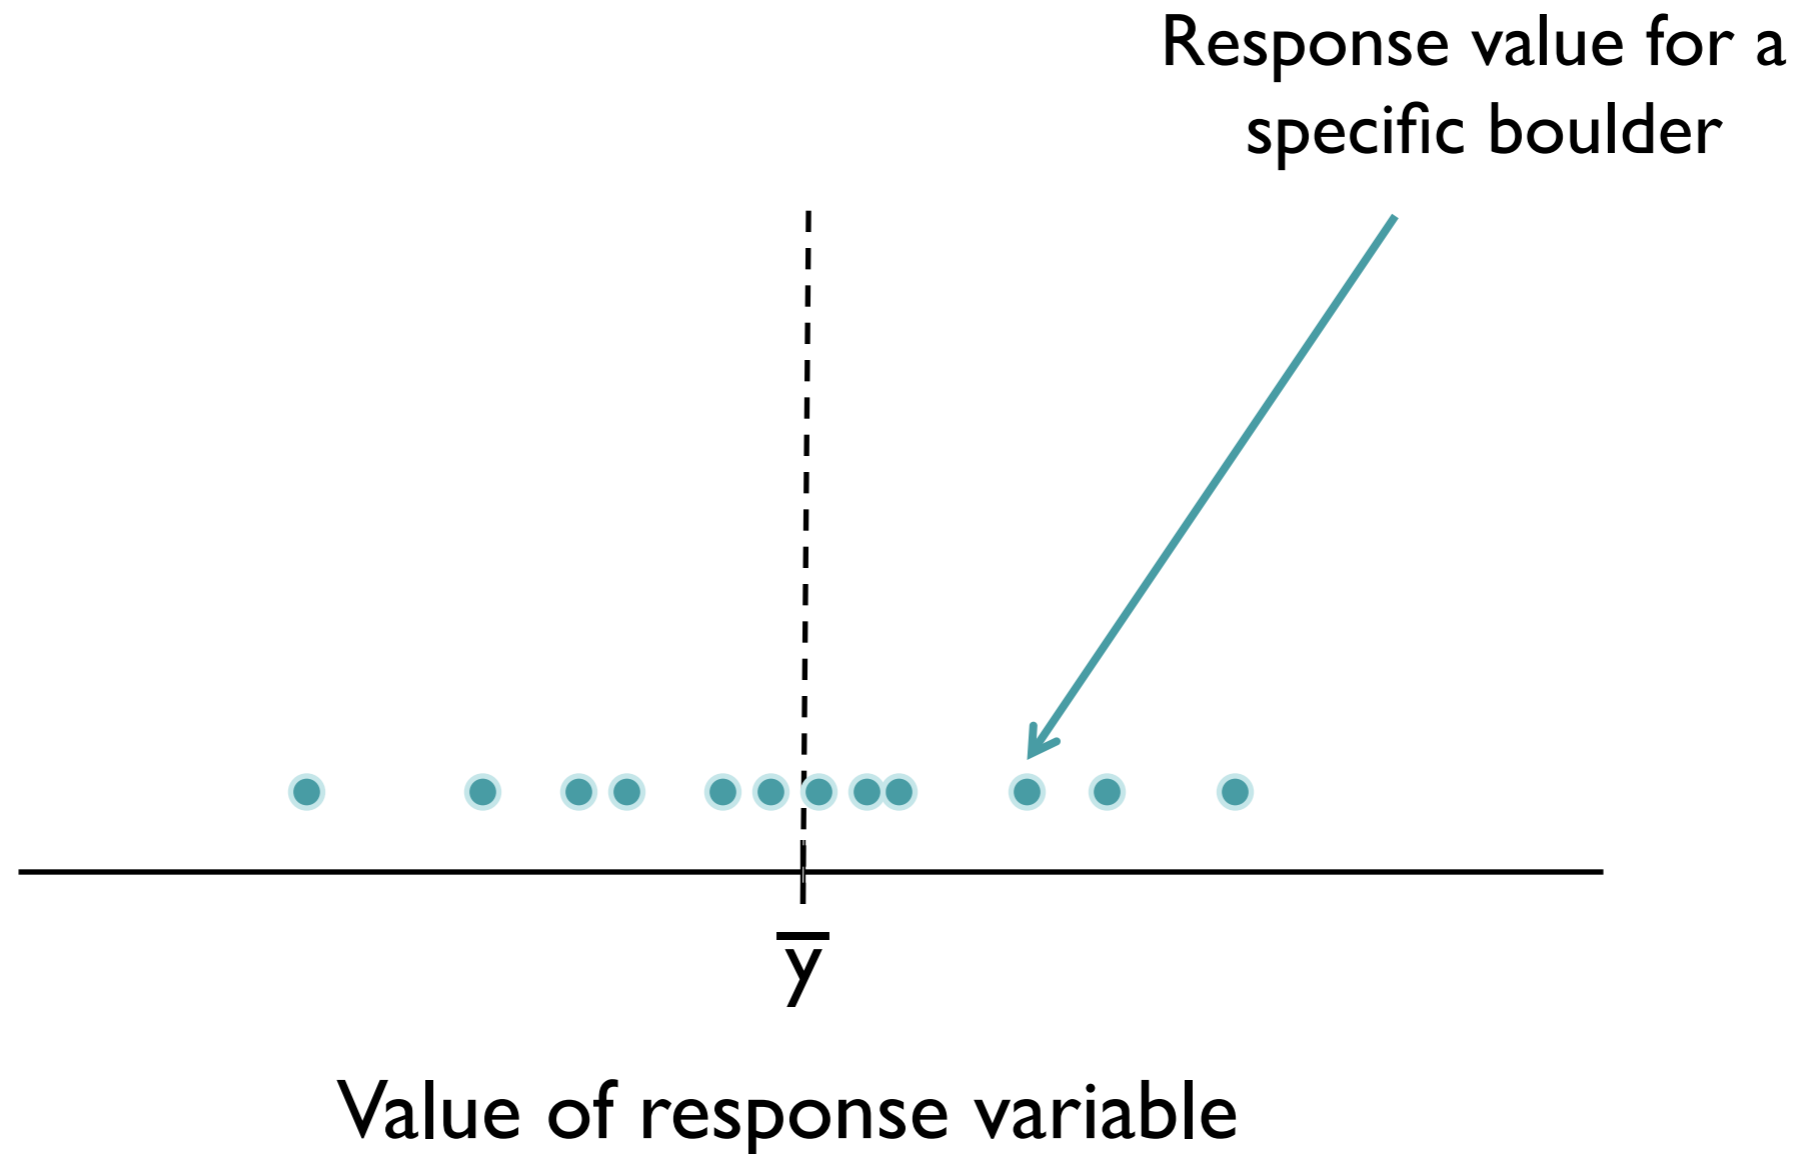

Challenge: Shared Environment for Whelks

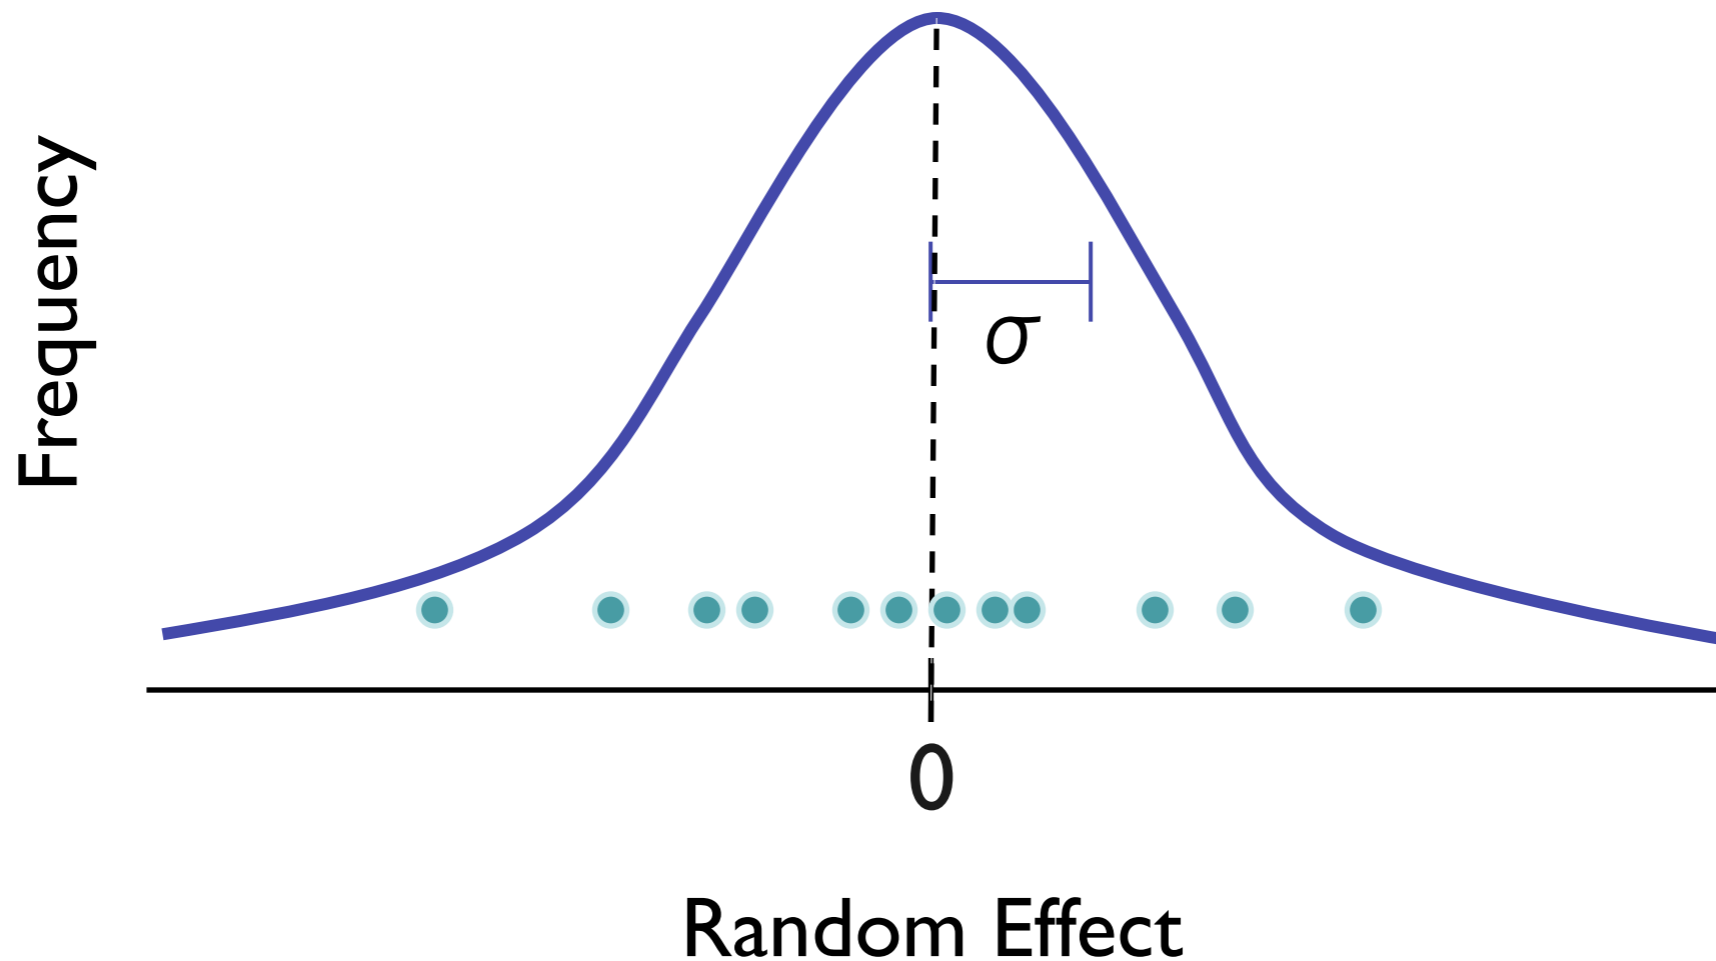

Challenge: Shared Environment for Whelks

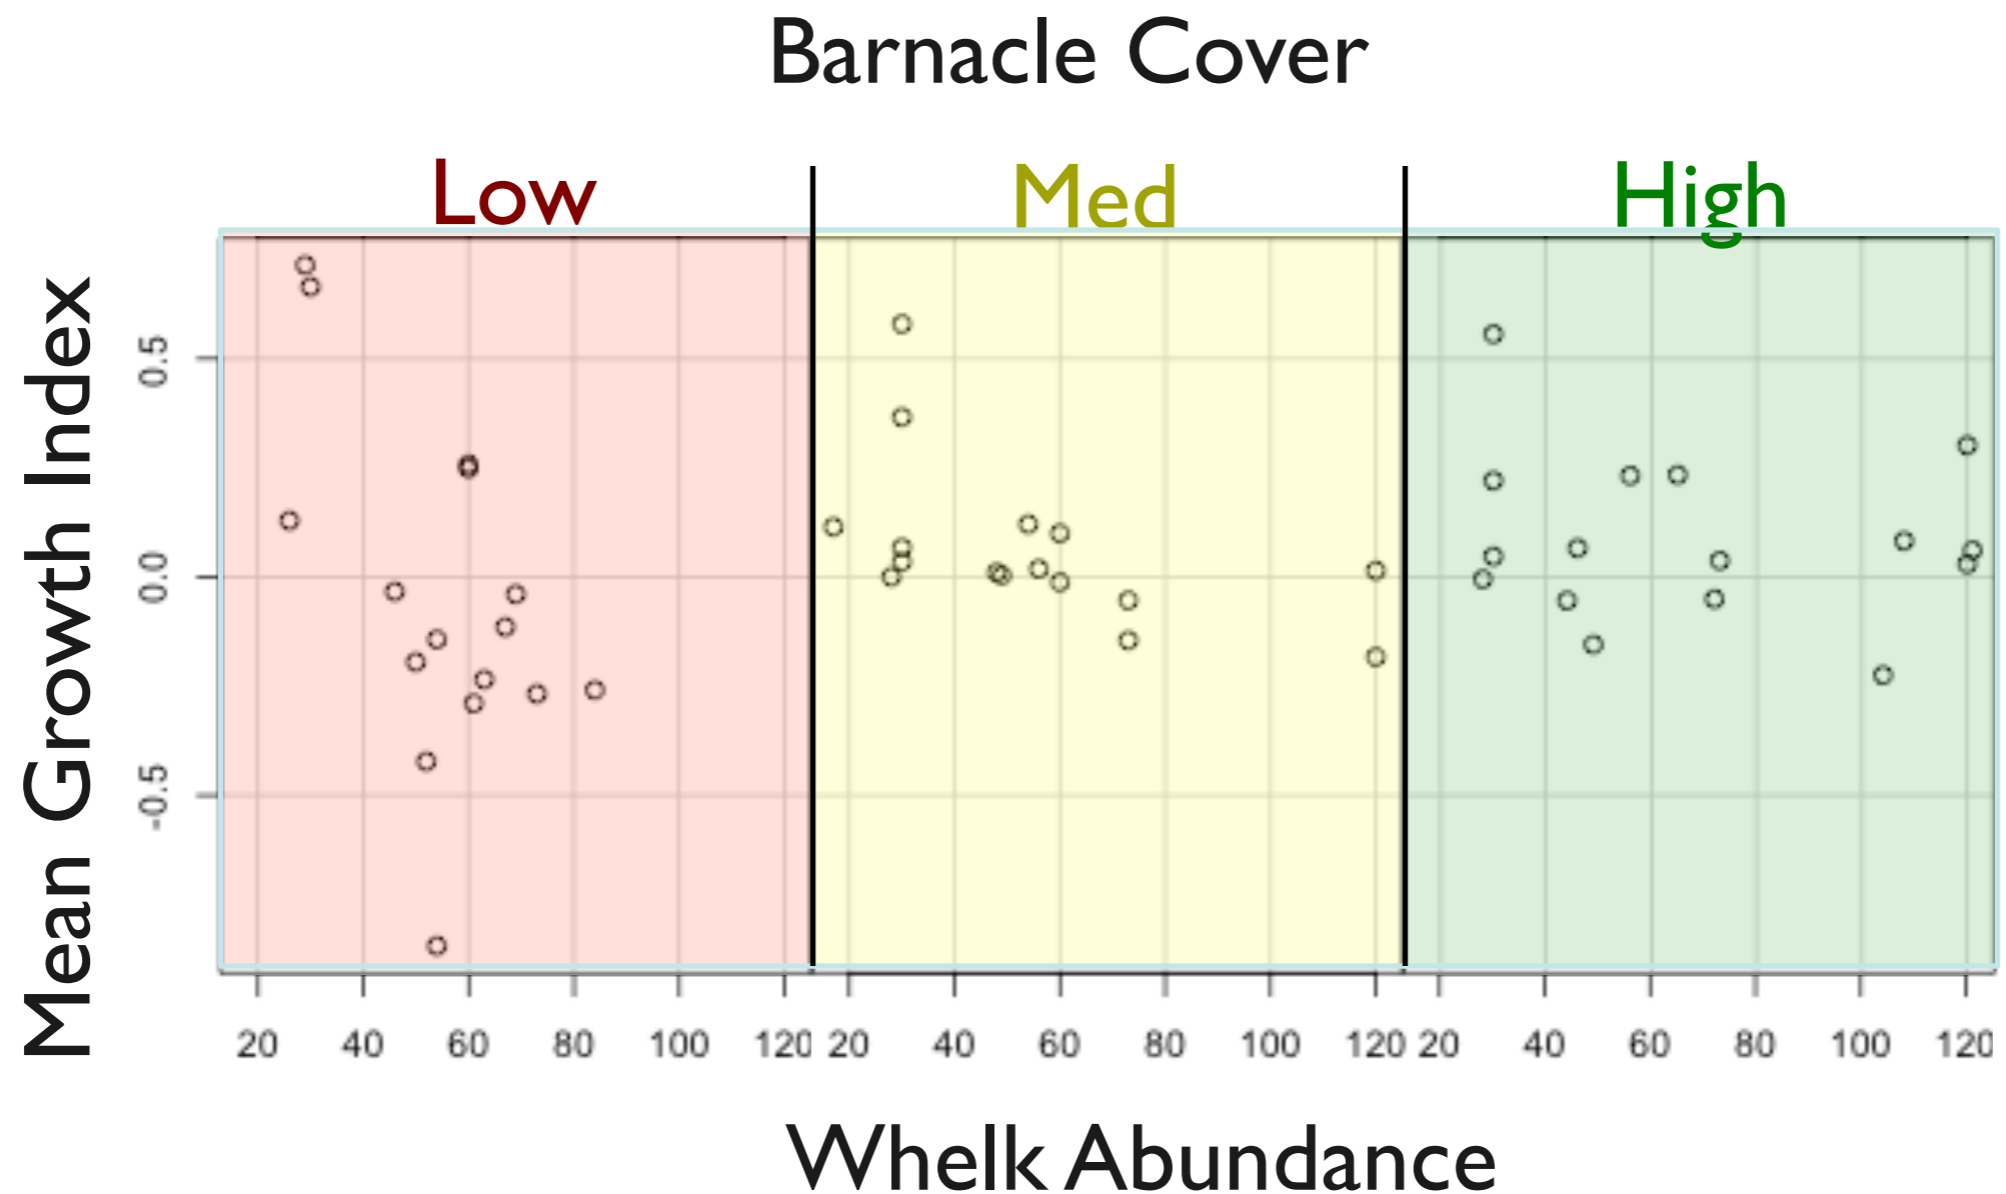

Solution: Add a Random Effect of Boulders into the Model

Solution: Add a Random Effect of Boulders into the Model

Results: Whelk Abundance and Barnacle Cover Effects on Growth

marginal $r^2 = 0.0417$

Effects on Whelks: Mortality

Challenge: Estimating Mortality from Census Data

Possible wheelk states:

- Alive and observed
- Alive and hidden
- Dead

} How do you tell which has occurred?

Solution: Develop Bayesian Mark Recapture Model

Bayesian framework:

$$\underbrace{P(\theta | \mathbf{x})}_{\text{Posterior}} \propto \underbrace{P(\mathbf{x} | \theta)}_{\text{Likelihood}} \underbrace{P(\theta)}_{\text{Prior}}$$

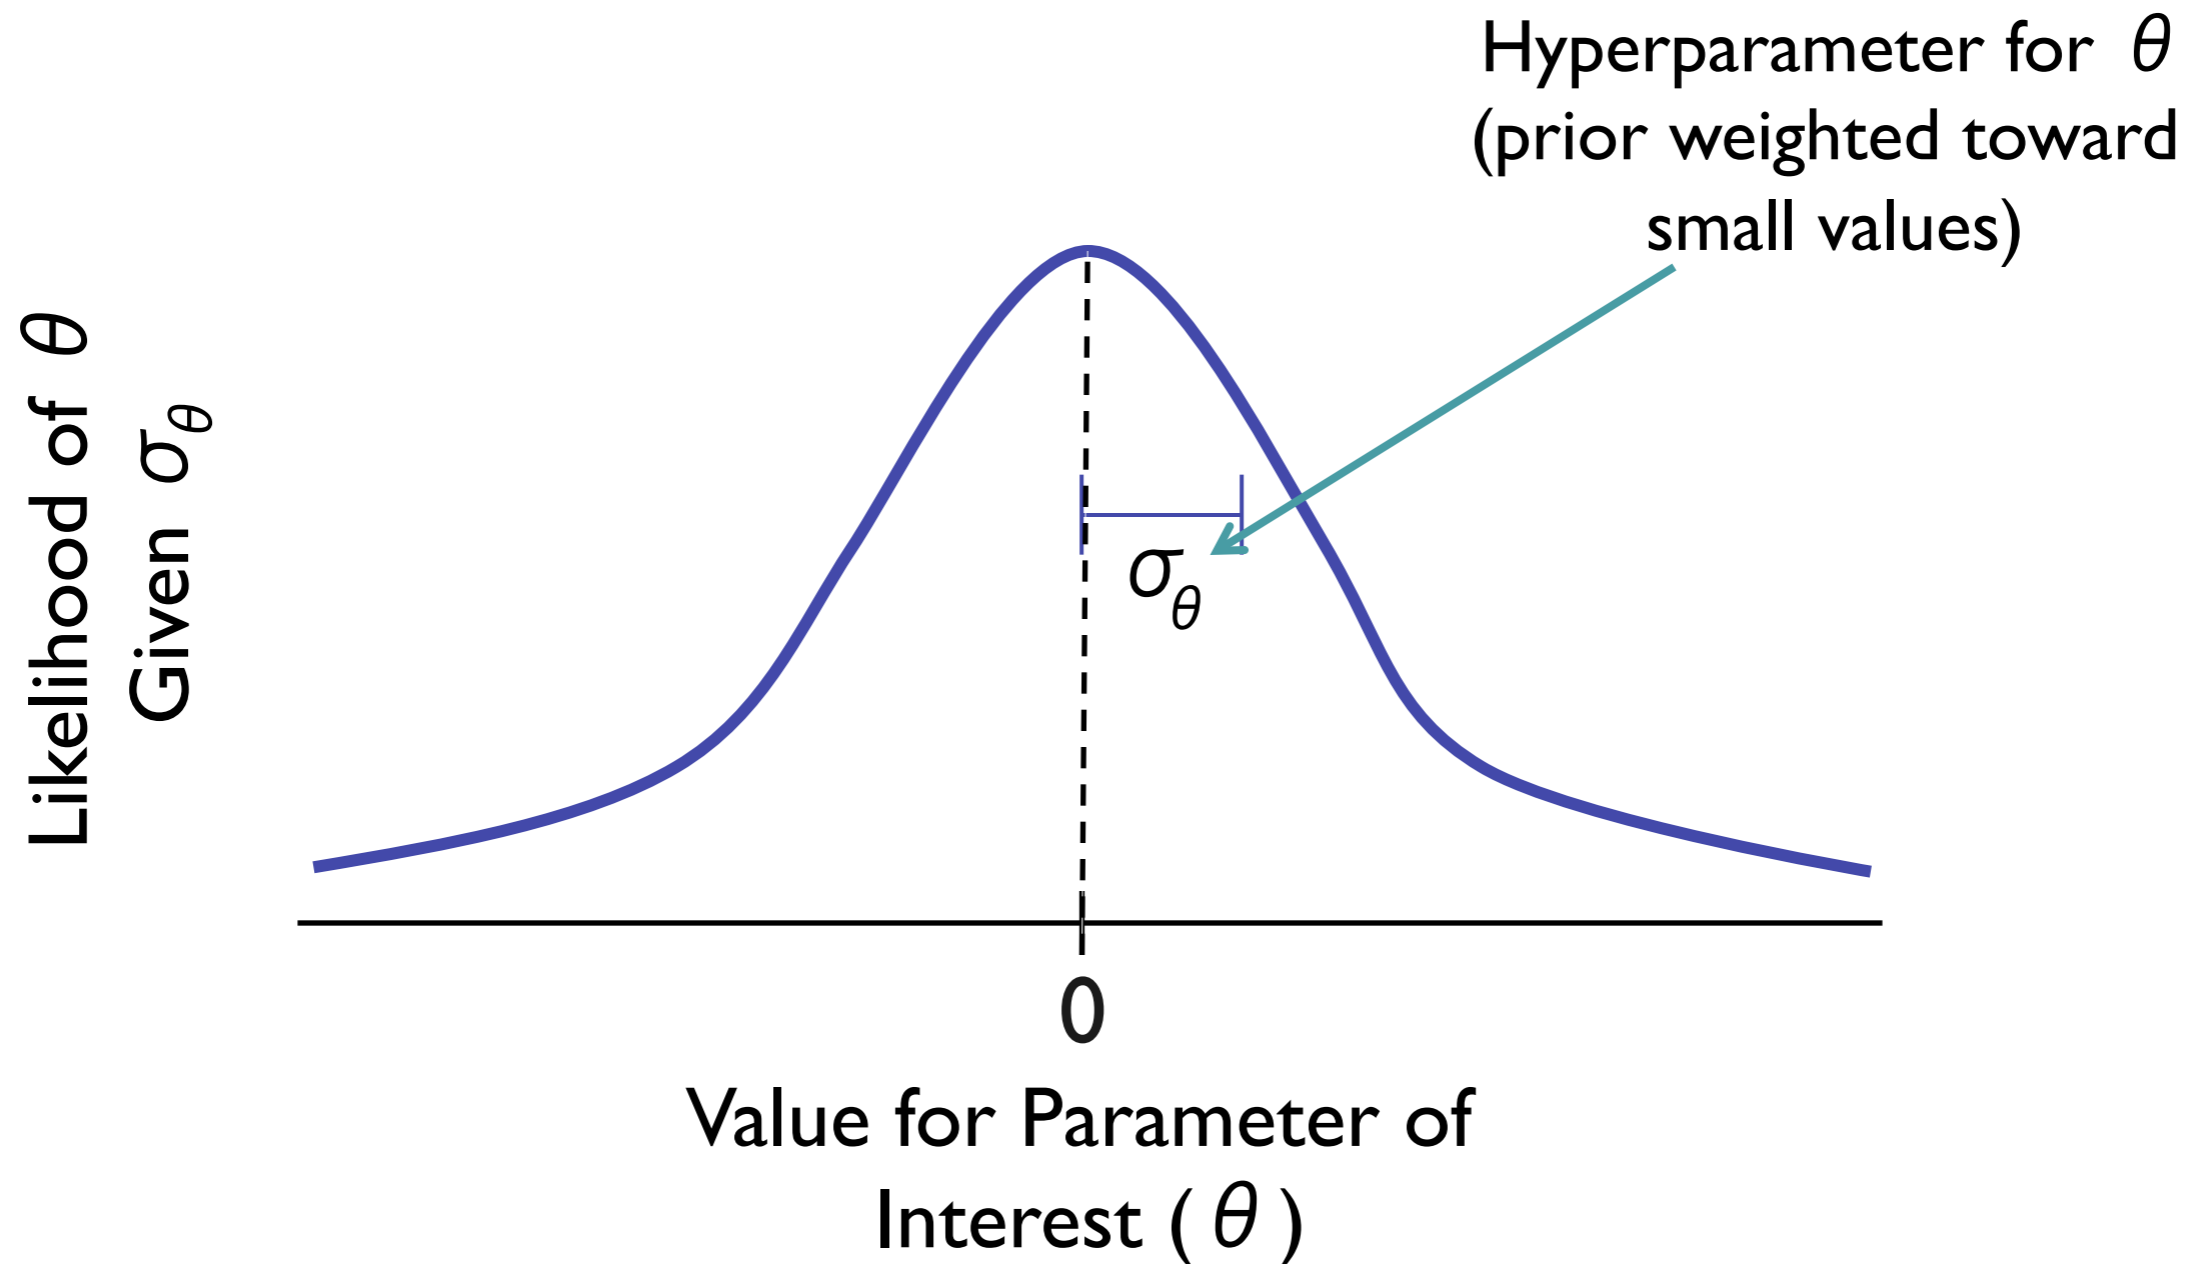

Basic model structure:

- Binomial mortality and recapture probabilities
- Mortality probability a function of predator and prey abundance
- Poisson process to account for immigration of new whelks

Challenge: Incorporate Variable Selection into Bayesian Analysis

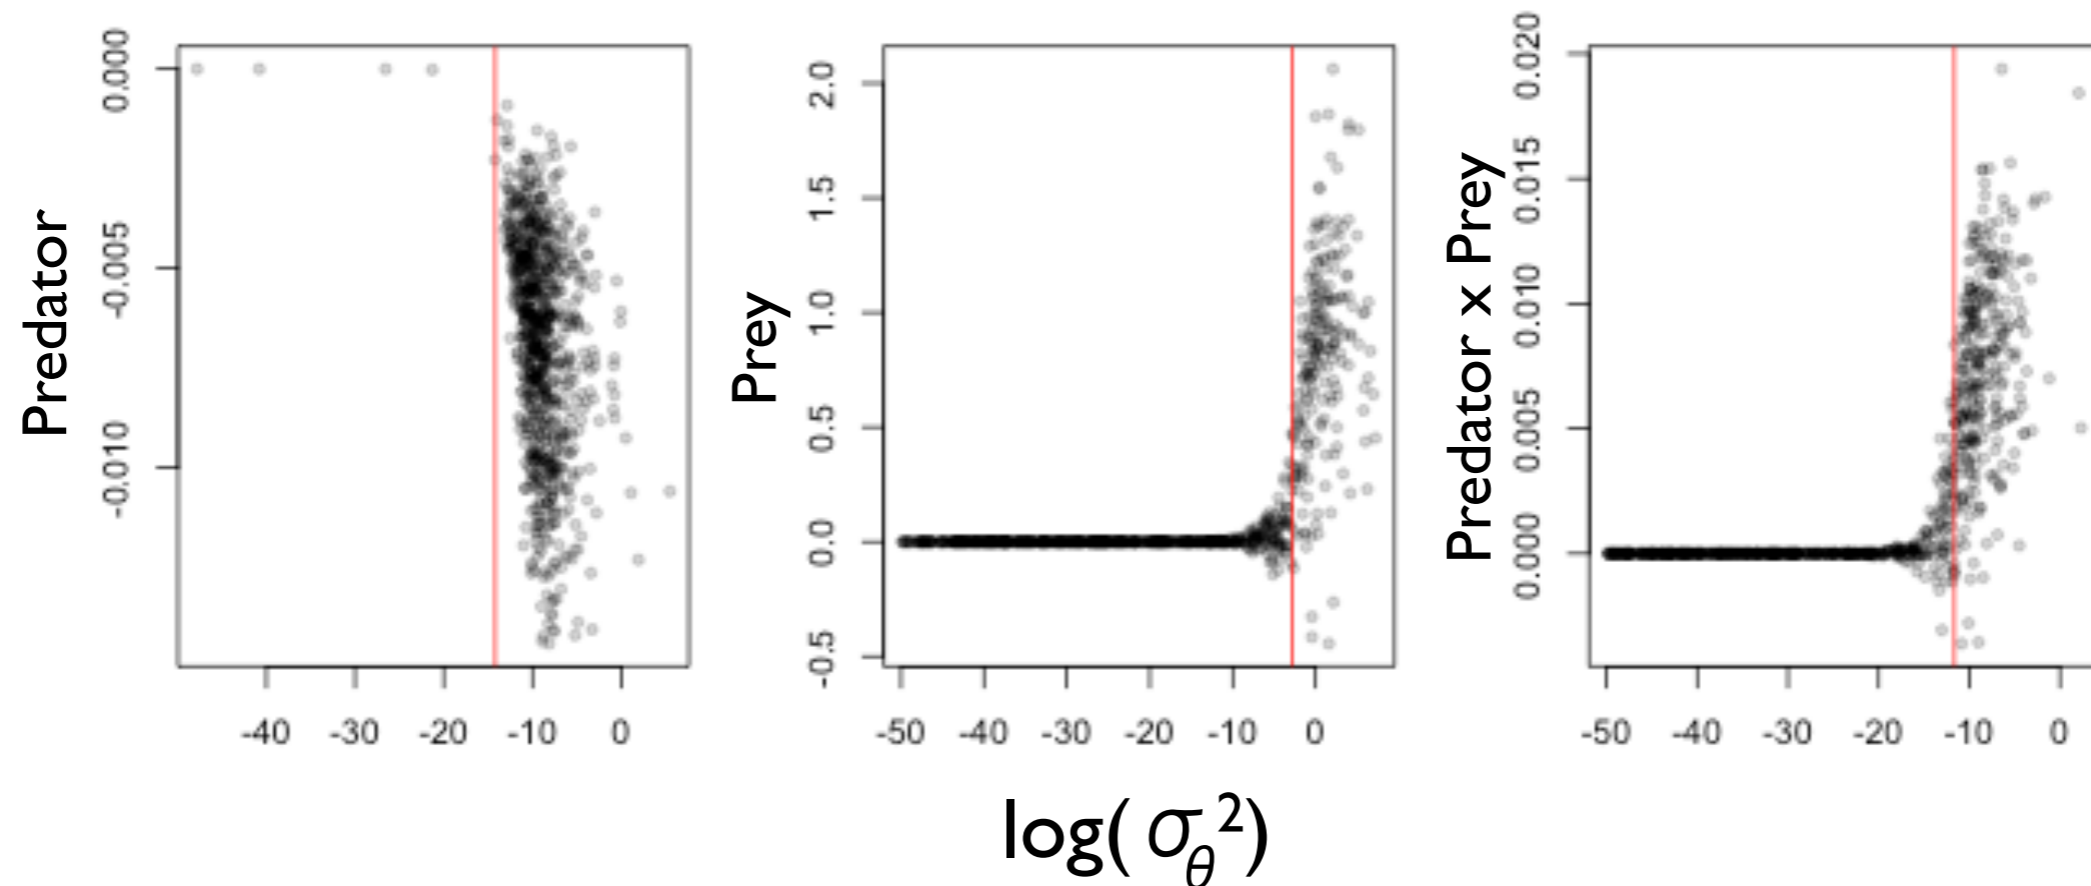

How do you measure the effect size for a variable (e.g., prey abundance) and at the same time assess whether it should be included in the model?

Solution: Adaptive Shrinkage

Results: Effects on Whelk Mortality

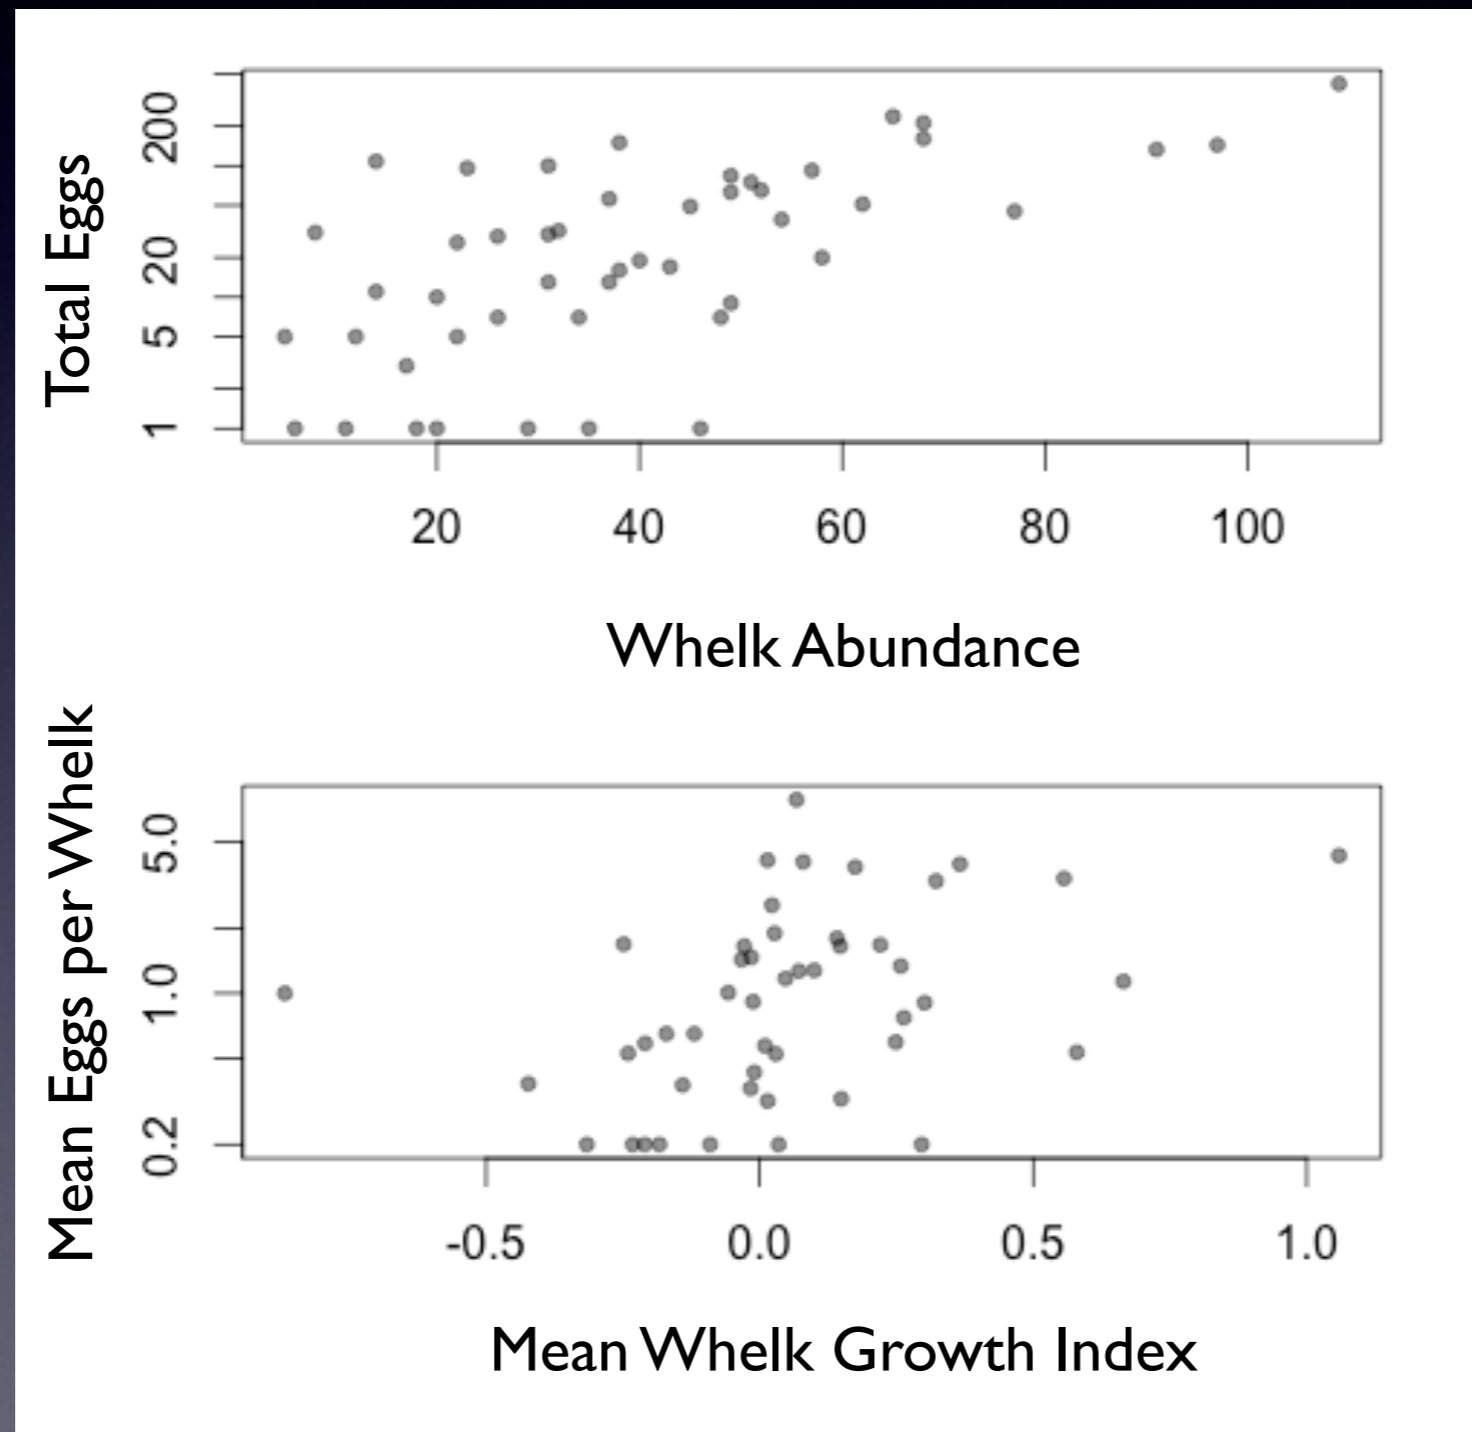

Posterior Model Coefficients

Variables Included in Posterior

	Prey Term	No Prey
Interaction Term	3.4%	39.2%
No Interaction	18.4%	42.5%

Effects on Whelks: Reproduction

Part I: Results

- No direct effects of prey abundance on whelk reproduction
- Prey abundance has weak but detectable effects on both whelk growth and mortality
- Whelk growth and reproduction are positively correlated

Part I: Take-aways

- Results of species removals don't necessarily predict effects of small changes in abundance
- We need mechanistic models that match the time scale of desired predictions

Part II: Regional Mortality

Results: Whelk Survival

Proportion surviving (log scale)

Part II: Results

- *Whelk* mortality varies significantly among regions
- Patterns of mortality are not easily explained by “standard culprits”
- Patterns of mortality appear to correspond to barnacle recruitment regimes

Part II: Take-aways

- Even basic life history of a species is not necessarily constant across its range
- Seasonal patterns of prey availability may shape the life history of short-lived predators

Conclusions

- We now have the tools to test long-held assumptions in community ecology
- We need mechanistic multispecies models that mesh short-term and long-term responses
- We need to pay more attention to regional variation in life history
